The Environmental Restoration of Hanford

Facts

Expedited Cleanup Project

Hexone Burial Ground

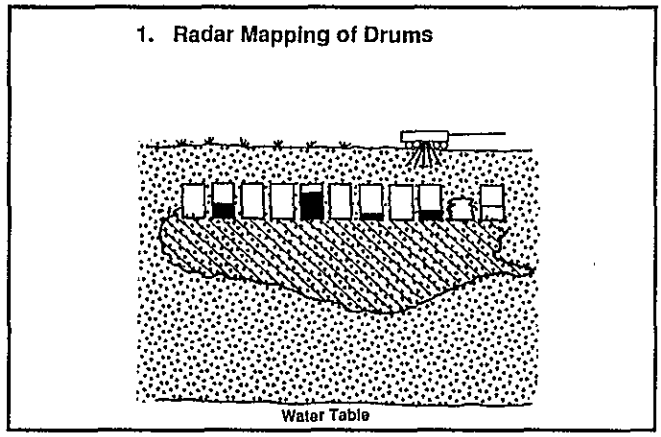
Many chemical and radioactive wastes were buried at Hanford in trenches, like the 618-9 Burial Ground. This burial ground is located a few miles north of Richland, Washington. About 5,000 gallons of organic solvent (primarily hexone) contaminated with uranium was buried here in about 100 55-gallon drums. The wastes were produced from research and development activities in the 300 Area.

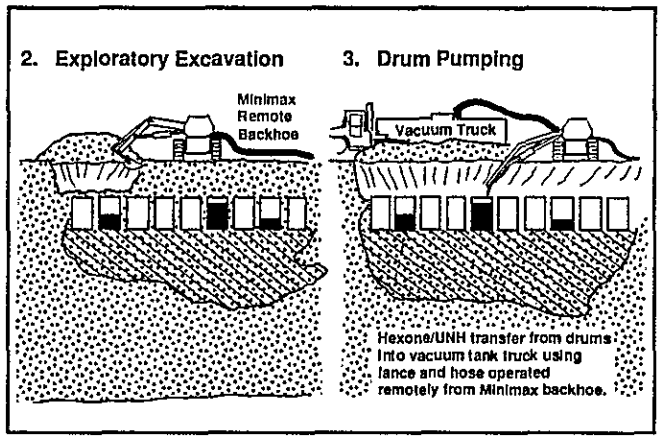
Because the drums have been in the ground for more than 30 years, they may not be entirely intact, and some or all of the liquid contained within them may have escaped. However, as no hexone has been detected in the groundwater around the burial ground, it is expected that the hexone has not yet leaked.

The burial ground can be cleaned up by digging up the drums, sampling and removing any liquids remaining in the drums and treating the soil around the drums if it has become contaminated. These activities will prevent the uranium-contaminated solvents from moving into the groundwater and from there, into the Columbia River. Taking this action now will save substantial costs compared to cleaning up the groundwater if it becomes contaminated.

This project is on a time critical schedule. Because hexone has a flashpoint of 70 degrees, the removal of any liquid remaining in the drums should be started during the early spring while outdoor temperatures are mild. Meeting this schedule hinges on all parties approving the start of activities at that time, and on the preparation of safety documents to begin digging up the drums. Due to the time-critical nature, the removal of liquids will be started before formal public comment occurs.

The following diagrams illustrate the expected steps for this project:





Several activities will be conducted to find out the nature and extent of contamination at the site. These activities will include, but are not limited to: conducting ground penetrating radar studies,

soil gas sampling, overburden excavation and drum sampling, and surrounding soil sampling (after excavation). Early studies of the site will determine the exact location of the drums, and soil gas surveys will indicate if organic vapors (from leaking drums) are present. The soil over the drums will be removed so the drums containing liquids can be pumped. This liquid will be stored in a tank for later analysis and treatment.

The plan of cleanup alternatives will evaluate the options of vitrifying any contaminated soil around the drums or burning the soil and disposing of it elsewhere. Other alternatives will also be studied. After DOE, EPA and Ecology review the alternatives, incorporate their comments and have the public review it, EPA will select the best cleanup alternative.

Activities to determine the exact number of drums and their locations are expected to begin in January 1991. The soil above the drums should be removed in the spring. All liquid from the drums will also be removed at that point. The liquid will be analyzed and stored for treatment until the cleanup proposal is approved. An analysis of the liquids and soil around the drums will help determine the best treatment method.

The entire project, including soil cleanup, is expected to last through fiscal year 1992.
